## The PCP question

 Which (positive) elements in a C\*-algebra are positive combinations of projections?(that is, linear combinations with positive coefficients.)

## The PCP question

 Which (positive) elements in a C\*-algebra are positive combinations of projections?(that is, linear combinations with positive coefficients.)

We were motivated by earlier work on:

Which (positive) elements in a C\*-algebra are the sum of projections? (Question still open in B(H). Recent interest due to frame theory.)

## The PCP question

 Which (positive) elements in a C\*-algebra are positive combinations of projections?(that is, linear combinations with positive coefficients.)

We were motivated by earlier work on:

Which (positive) elements in a C\*-algebra are the sum of projections? (Question still open in B(H). Recent interest due to frame theory.)

Of course, we first need to know:

Which elements in a C\*-algebra are linear combinations of projections?

 Fillmore (1967) Every operator in B(H) is a linear combination of 257 projections. Pearcy & Topping (1967), Paszkiewicz (1980), Matsumoto (1984) reduced the number to 10 projections.

 Fillmore (1967) Every operator in B(H) is a linear combination of 257 projections. Pearcy & Topping (1967), Paszkiewicz (1980), Matsumoto (1984) reduced the number to 10 projections.

Fillmore (1967) Positive invertibles are PCP.

- Fillmore (1967) Every operator in B(H) is a linear combination of 257 projections. Pearcy & Topping (1967), Paszkiewicz (1980), Matsumoto (1984) reduced the number to 10 projections.
- ► Fillmore (1967) Positive invertibles are PCP.
- ► A different proof by Fong & Murphy (1985) using "bounds on the coefficients" of the linear combinations.

Finite C\*-algebras: linear combinations

 ${\mathcal A}$  a C\*-algebra with the listed properties/

#### Theorem

 $\mathcal{A}$  is the linear span of it projections with "control on the coefficients". That is, there is a constant  $V_0$  s.t. for every  $b \in \mathcal{A}$ ,  $\exists \lambda_j \in \mathbb{C}, p_j \in \mathcal{A}$  projections s.t

$$b = \sum_{1}^{n} \lambda_{j} p_{j}$$
 and  $\sum_{1}^{n} |\lambda_{j}| \leq V_{0} \|b\|$ .

Finite C\*-algebras: linear combinations

 ${\mathcal A}$  a C\*-algebra with the listed properties/

#### Theorem

 $\mathcal{A}$  is the linear span of it projections with "control on the coefficients". That is, there is a constant  $V_0$  s.t. for every  $b \in \mathcal{A}$ ,  $\exists \lambda_j \in \mathbb{C}, p_j \in \mathcal{A}$  projections s.t

$$b = \sum_{1}^{n} \lambda_{j} p_{j}$$
 and  $\sum_{1}^{n} |\lambda_{j}| \leq V_{0} \|b\|$ .

#### Question

If A is the span of its projections, does control of the coefficients follow automatically?

### Why control of the coefficients?

Lemma (proof as in Fong & Murphy's (1985) for B(H)) If a C\*-algebra  $A^+$  is the span of it projections with control on the coefficients and has RR(A) = 0, then every positive invertible is PCP.

## Why control of the coefficients?

Lemma (proof as in Fong & Murphy's (1985) for B(H)) If a C\*-algebra  $A^+$  is the span of it projections with control on the coefficients and has RR(A) = 0, then every positive invertible is PCP.

Beyond invertibles:

#### Lemma

Let A have the property that positive invertibles in any corner rAr are PCP. If  $b := \alpha p \oplus a$  with  $\alpha > ||a||$  and  $a = qaq \ge 0$ ,  $q \preceq p$ , then b is PCP.

## Why control of the coefficients?

Lemma (proof as in Fong & Murphy's (1985) for B(H)) If a C\*-algebra  $A^+$  is the span of it projections with control on the coefficients and has RR(A) = 0, then every positive invertible is PCP.

Beyond invertibles:

#### Lemma

Let A have the property that positive invertibles in any corner rAr are PCP. If  $b := \alpha p \oplus a$  with  $\alpha > ||a||$  and  $a = qaq \ge 0$ ,  $q \preceq p$ , then b is PCP.

This lemma is the essential tool for attacking the general PCP problem.

#### First step: commutators

# Theorem If $b \in A$ and $\tau(b) = 0 \quad \forall \tau \in T(A)$ , then b is the sum of 2 commutators (with control on their norms.)

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

#### First step: commutators

Theorem If  $b \in A$  and  $\tau(b) = 0 \quad \forall \tau \in T(A)$ , then b is the sum of 2 commutators (with control on their norms.)

This theorem holds even when  $card(Ext(T(A)) = \infty)$ .

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

### Ingredients in the proof

Embed in A a unital simple AH-algebra C with real rank zero and dimension growth bounded by 3 and same K-invariants (Lin (2001), Elliott& Gong, Gong (1996, 1997,1998)). (Here is the only place where we use separability.)

### Ingredients in the proof

- Embed in A a unital simple AH-algebra C with real rank zero and dimension growth bounded by 3 and same K-invariants (Lin (2001), Elliott& Gong, Gong (1996, 1997,1998)). (Here is the only place where we use separability.)
- Extend the Fack (1982), Thomsen (1994) construction to this inductive limit case so to approximate b by a bounded number of commutators.

### Ingredients in the proof

- Embed in A a unital simple AH-algebra C with real rank zero and dimension growth bounded by 3 and same K-invariants (Lin (2001), Elliott& Gong, Gong (1996, 1997,1998)). (Here is the only place where we use separability.)
- Extend the Fack (1982), Thomsen (1994) construction to this inductive limit case so to approximate b by a bounded number of commutators.
- Use the Marcoux (2002, 2006) machinery to express b as the sum of commutators and then reduce their number to two. (Still keep control on the norms.)

### From commutators to projections

▶ Marcoux (2002) proved that if in a C\*-algebra there exist three mutually orthogonal projections  $p_1, p_2$  and  $p_3$  such that  $1 = p_1 + p_2 + p_3$  and  $p_i \preceq 1 - p_i$  for  $1 \le i \le 3$ , then every commutator is a linear combination of 84 projections, with control on the coefficients. (Commutators = sums of certain nilpotents of order two=sums of idempotents = (by Davidson) =linear combinations of projections)

### From commutators to projections

▶ Marcoux (2002) proved that if in a C\*-algebra there exist three mutually orthogonal projections  $p_1, p_2$  and  $p_3$  such that  $1 = p_1 + p_2 + p_3$  and  $p_i \preceq 1 - p_i$  for  $1 \le i \le 3$ , then every commutator is a linear combination of 84 projections, with control on the coefficients. (Commutators = sums of certain nilpotents of order two=sums of idempotents = (by Davidson) =linear combinations of projections)

This condition is easily satisfied in our case. Thus so far we have:

► every b ∈ A s.t. τ(b) = 0 for every tracial state τ is a linear combination of projections with control on the coefficients.

### Beyond zero trace

If there is a unique tracial state *τ*, then
 *b* = *τ*(*b*)1 + (*b* − *τ*(*b*)1) is a linear combination of projections
 (just one...) plus a zero-trace element.

## Beyond zero trace

- If there is a unique tracial state *τ*, then
  *b* = *τ*(*b*)1 + (*b* − *τ*(*b*)1) is a linear combination of projections
  (just one...) plus a zero-trace element.
- ► Using the density of K<sub>o</sub>(A) in the continuous affine functions on T(A) (Blackadar (1982)) we get:

#### Lemma

If card( $Ext(T(A)) < \infty$  then every element in A is the sum of linear combination of projections plus an element in the kernel of all the traces.

## Beyond zero trace

- If there is a unique tracial state *τ*, then
  *b* = *τ*(*b*)1 + (*b* − *τ*(*b*)1) is a linear combination of projections
  (just one...) plus a zero-trace element.
- ► Using the density of K<sub>o</sub>(A) in the continuous affine functions on T(A) (Blackadar (1982)) we get:

#### Lemma

If card( $Ext(T(A)) < \infty$  then every element in A is the sum of linear combination of projections plus an element in the kernel of all the traces.

These 3 steps conclude the proof. To recap:
 b= linear combination of projections + c, τ(c) = 0∀τinT(A);
 c = [x<sub>1</sub>, y<sub>1</sub>] + [x<sub>2</sub>, y<sub>2</sub>];
 [x<sub>i</sub>, y<sub>i</sub>]= linear combination of projections;

and all that with control of the coefficients.

Infinitely many extremal traces?

The condition that  $card(Ext(T(A)) < \infty$  is essential:

・ロト < 団ト < 三ト < 三ト ・ 三 ・ のへの</li>

## Infinitely many extremal traces?

The condition that  $card(Ext(T(A)) < \infty$  is essential:

#### Proposition

If  $card(Ext(T(A)) = \infty$  and the collection D(A) of Murray-von Neumann equivalence classes of projections of A is countable, then A is not the linear span of its projections.

## Infinitely many extremal traces?

The condition that  $card(Ext(T(A)) < \infty$  is essential:

#### Proposition

If  $card(Ext(T(A)) = \infty$  and the collection D(A) of Murray-von Neumann equivalence classes of projections of A is countable, then A is not the linear span of its projections.

The proof mimics the one that a Hamel basis of an infinite separable Banach space cannot be countable.

When b ∈ A, its range projection R<sub>b</sub> exists in A<sup>\*\*</sup> (it is an open projection).

・ロト・日本・モート モー うへぐ

- When b ∈ A, its range projection R<sub>b</sub> exists in A<sup>\*\*</sup> (it is an open projection).
- Every (finite, faithful) trace τ has an extension τ to a (not necessarily faithful nor finite) tracial weight on (A<sup>\*\*</sup>)<sup>+</sup> (Combes(1968)- Ortega, Rordam, Thiel (2011))

- When b ∈ A, its range projection R<sub>b</sub> exists in A<sup>\*\*</sup> (it is an open projection).
- Every (finite, faithful) trace τ has an extension τ̄ to a (not necessarily faithful nor finite) tracial weight on (A<sup>\*\*</sup>)<sup>+</sup> (Combes(1968)- Ortega, Rordam, Thiel (2011))
- ► The condition that \(\bar{\tau}(R\_b) < \infty \(\forall \tau \in T(\mathcal{A})\) is necessary for b to be a linear combination of projections. Indeed:</p>

$$b = \sum \lambda_j p_j \Rightarrow \bar{\tau}(R_b) \leq \bar{\tau}(\bigvee p_j) \leq \sum \tau(p_j) < \infty \ \forall \tau \in T(\mathcal{A})$$

The condition is also sufficient. But first, we need the PCP result.

Finite C\*-algebras: N&S condition for PCP

#### Theorem

Let  $\mathcal{A}$  be  $\sigma$ -unital, with all properties as above and  $card(Ext(T(\mathcal{A})) < \infty$ . Then  $b \in \mathcal{A}^+$  is PCP if and only if  $\overline{\tau}(R_b) < \infty \ \forall \tau \in T(\mathcal{A}).$  (Always true if  $\mathcal{A}$  is unital.)

Finite C\*-algebras: N&S condition for PCP

#### Theorem

Let  $\mathcal{A}$  be  $\sigma$ -unital, with all properties as above and  $card(Ext(T(\mathcal{A})) < \infty$ . Then  $b \in \mathcal{A}^+$  is PCP if and only if  $\overline{\tau}(R_b) < \infty \ \forall \tau \in T(\mathcal{A}).$ (Always true if  $\mathcal{A}$  is unital.)

#### Corollary

With  $\mathcal{A}$  as above,  $b \in \mathcal{A}$  is a linear combination of projections in  $\mathcal{A}$  if and only if  $\overline{\tau}(R_b) < \infty \ \forall \tau \in T(\mathcal{A})$ .

## Ingredients in the proof, part I

We can work in a corner where the "identity is not too far from the range projection".

#### Lemma

If  $\bar{\tau}(R_b) < \infty \ \forall \tau \in T(\mathcal{A})$  then there is a trace preserving isomorphism

 $\Psi$ : her(b)  $\rightarrow \Psi$ (her(b))  $\subset r\mathcal{A}r$  for some  $r \in \mathcal{A}, \ \tau(r) < 2\overline{\tau}(R_b)$ .

## Ingredients in the proof, part I

We can work in a corner where the "identity is not too far from the range projection".

#### Lemma

If  $\bar{\tau}(R_b) < \infty \ \forall \tau \in T(\mathcal{A})$  then there is a trace preserving isomorphism

 $\Psi$ : her(b)  $\rightarrow \Psi$ (her(b))  $\subset r\mathcal{A}r$  for some  $r \in \mathcal{A}, \ \tau(r) < 2\overline{\tau}(R_b)$ .

Why solving PCP question first? Notice that

- decomposing Ψ(b) into a PCP in rAr, necessarily in Ψ(her(b)) gives a PCP decomposition of b;
- decomposing  $\Psi(b)$  into a linear combination of projections in rAr does not yield a decomposition of b.

### Ingredients in the proof, part II

Previous lemma permits to embed b into a unital algebra so that \(\overline{\tau}\) | N<sub>b</sub> | < \(\overline{\tau}\) | ∀\(\tau\) ∈ T(\(\mathcal{A}\)).</p>

### Ingredients in the proof, part II

- Previous lemma permits to embed b into a unital algebra so that \(\overline{\tau}\) | N<sub>b</sub> | < \(\overline{\tau}\) | ∀\(\tau\) ∈ T(\(\mathcal{A}\)).</p>
- ▶ By Brown's interpolation theorem find projections  $p \perp q$  in T(A) with  $N_b \leq q \preccurlyeq p \leq R_b$

### Ingredients in the proof, part II

- Previous lemma permits to embed b into a unital algebra so that \(\overline{\tau}\) | N<sub>b</sub> | < \(\overline{\tau}\) | ∀\(\tau\) ∈ T(\(\mathcal{A}\)).</p>
- By Brown's interpolation theorem find projections p ⊥ q in T(A) with N<sub>b</sub> ≤ q ≍ p ≤ R<sub>b</sub>
- Use the key lemma that we have seen before:

#### Lemma

Let A have the property that positive invertibles in any corner rAr are PCP. If  $b := \alpha p \oplus a$  with  $\alpha > ||a||$  and  $a = qaq \ge 0$ ,  $q \preceq p$ , then b is PCP.

Plus more work - the proof is technical.
