Abstract. In this paper, we propose a multiphase fuzzy region competition model for texture image segmentation. In the functional, each region is represented by a fuzzy membership function and a probability density function that is estimated by a non-parametric kernel density estimation. The overall algorithm is very efficient as both the fuzzy membership function and the probability density function can be implemented easily. We apply the proposed method to synthetic and natural texture images, and synthetic aperture radar images. Our experimental results have shown that the proposed method is competitive with the other state-of-the-art segmentation methods.

1 Introduction

Image segmentation is a fundamental task in image processing and computer vision. It is aimed to partition an image into a finite number of subregions with homogeneous intensity (color, texture) properties which will hopefully correspond to objects or object parts. Approaches based on the calculus of variation and partial differential equations (PDEs) are powerful in image segmentation. One important reason of their success is that these models are flexible in integrating the geometric information such as shape, length and area. The best known and most influential approaches are Mumford-Shah

In this paper, we focus on the segmentation of texture images. Piecewise smooth/constant models such as Mumford-Shah model [20] and Chan-Vese model [7] fail in this case. Recently, some variational methods have been proposed to tackle the segmentation of complex textures based on feature extraction techniques [9, 14, 25, 27]. In [9, 27], a set of Gabor filters with different scales, orientations and frequencies are applied to the image to create the features to represent texture in the image. Chan et al. in [9] extended the Chan-Vese model to these vector features for texture image segmentation. Because there are many features to be used in the model, the corresponding minimization method can be slow. Savig et al. [27] used the Beltrami framework on the texture features to define a new texture indicator function, and then integrated this function in a combined model of the geodesic active contour [5] and the vectorial Chan-Vese model [7] to segment textural regions. Rousson et al. [25] extracted the texture features by applying an anisotropic diffusion process to the structure tensor. In their segmentation framework, a Gaussian approximation is used for all the features channels, and a nonparametric approximation is used for the first gray image channel. The choice of Gaussian approximation restricts the applicability to limited set of images that satisfy the underlying assumption.

Another kind of variational methods for texture image segmentation is based on region competition. Zhu et al. [31] proposed a region competition method unifying snake, region growing and Bayesian statistics. It is a parametric model since they assume that each region follows a Gaussian distribution. Kim et al. in [16] proposed a nonparametric statistical method for image segmentation using mutual information and curve evolution. However, the above mentioned variational approaches have some practical shortcomings. The above energy functionals are not convex in the optimization space (usually the characteristic functions of sets, which is nonconvex collection) and they have local minima. Typically, the gradient decent method is used in the implementation of these models, and are therefore prone to getting stuck in these local minima. Hence these methods are sensitive to initialization. Meanwhile, the implementation of the above models are based on curve evolution and level set approach [22]. The drawback in the level set implementation consists of initializing the active contour in a distance function and re-initializing periodically during the evolution, which is time-consuming.

Based on the observation in the Rudin-Osher-Fatemi [26] model for binary image denoising and Chan-Vese segmentation model, the drawback of leading to local minima comes from the non-convexity of characteristic functions. Recently, Chan et al. [10] proposed to use a “segmentation” variable valued in [0,1] to substitute a characteristic function and obtain a new constrained convex functional such that the global minimizer can be achieved in the segmentation process. To make the algorithm more efficient, Bresson et al. [2] proposed to add another new variable to approximate “segmentation” variable such that the Chambolle’s fast dual projection method [6] can be employed. The advantage of this algorithm is that it is fast and easy to implement. There are several works following this idea [3, 4, 14, 18, 19]. Mory et al. [18, 19] derived the fuzzy region competi-
tion method, parametric and nonparametric statistics error functions in the region terms are considered and studied respectively. Ni et al. [4] used histogram and Wasserstein distance in the region term. Houhou et al. [14] used shape operator borrowed from different geometry to extract only one texture feature and then used the popular Kullback-Leibler distance in the region term. We remark that the above techniques are only used in two-phase image segmentation.

In [28], Shen developed a multiphase stochastic variational soft segmentation Mumford-Shah model employed a double well potential regularization term in the model. As a set of partial differential equations arising from the model have to be solved, the resulting method is computationally expensive. This method may not be handled a more complicated texture image segmentation problem.

In this paper, we propose a multiphase fuzzy region competition model for texture image segmentation. In the functional, each region is represented by a fuzzy membership function and a probability density function. The fuzzy membership function is used to represent the region such that the energy functional is convex with respect to membership functions. The probability density function is estimated in each region by using kernel density method. The estimation method is different from [16, 19]. The overall algorithm is very efficient as both the fuzzy membership function and the probability density function can be implemented easily. We apply the proposed method to synthetic and natural texture images, and synthetic aperture radar images. Our experimental results have shown that the proposed method is competitive with the other state-of-the-art segmentation methods.

The outline of the paper is as follows. We review some related work for texture image segmentation in Section 2. In Section 3, we propose our method and the numerical algorithm. Experimental results on various images are showed in Section 4. Finally, we conclude our paper in Section 5.

2 Related works

The general $N$-phase segmentation problem can be formulated as follows: Given an image $I: \Omega \to \mathbb{R}$, where the image domain $\Omega$ is a bounded and open subset of $\mathbb{R}^2$, the aim is to partition $\Omega$ into $N$ regions $\{\Omega_i\}_{i=1}^N$, such that $\Omega_i \cap \Omega_j = \emptyset, j \neq i$, and $\bigcup_{i=1}^N \Omega_i = \Omega$ by certain suitable measure. We review some texture image segmentation methods which are closely related to our method.

2.1 Region competition

Zhu and Yuille [31] proposed to minimize the following energy

$$F(\Gamma, \{\alpha_i\}) = \sum_{i=1}^{N} \left\{ \frac{H}{2} \int_{\partial \Omega_i} ds - \int_{\Omega_i} \log P_i(1|\alpha_i) dx \right\}.$$

(2.1)
The first term within the braces is the length of the boundary curve \( \partial \Omega_i \) for region \( \Omega_i \). 
\[
\Gamma = \bigcup_{i=1}^N \partial \Omega_i \text{ is the segmentation boundaries of the entire image.}
\]
The second term is the sum of the cost for coding the intensity \( I \) into region \( \Omega_i \) by the conditional probability distributions \( -\log P_i(I|\alpha_i) \), where \( \alpha_i \) is the parameter in the probability density function \( P_i \). Usually a Gaussian probability density function is considered
\[
P_i(I|\alpha_i) = \frac{1}{\sqrt{2\pi\sigma_i^2}} \exp\left(-\frac{(I-\mu_i)^2}{2\sigma_i^2}\right),
\]
where \( \alpha_i = (\mu_i, \sigma_i) \) are scalar parameters. Curve evolution technique is used in the implementation to solve the optimization problem in (2.1).

### 2.2 Two phase fuzzy region competition

In order to solve a general two-phase region competition problem as minimizing
\[
F(\Gamma, \alpha_1, \alpha_2) = \int_{\partial \Omega} ds + \lambda \int_{\Omega_1} r_1^{\alpha_1} dx + \lambda \int_{\Omega_2} r_2^{\alpha_2} dx,
\]
where the image region \( \Omega \) is partitioned into \( \Omega_1 \) and \( \Omega_2 \), \( \alpha_i \) is the region parameter of the region \( \Omega_i \), and \( r_i^{\alpha_i} \) is error function, Mory et al. [18] proposed to use fuzzy membership function \( u \in BV_{[0,1]}(\Omega) \) to represent the region and minimize the two-phase fuzzy region competition energy instead
\[
F(u, \alpha_1, \alpha_2) = \int_{\Omega} |\nabla u| dx + \lambda \int_{\Omega_1} ur_1^{\alpha_1} dx + \lambda \int_{\Omega_2} (1-u)r_2^{\alpha_2} dx.
\]
(2.2)
The fast dual projection method proposed by Chambolle [6] is introduced to solve the problem. The error functions in Chan-Vese model [7] \( r_i^{\alpha_i} = (I-c_i)^2 \), and the local version are studied in the paper.

In the later work [19], Mory et al. considered nonparametric probability density function as an error function and minimize
\[
F(u, p_1, p_2) = \int_{\Omega} |\nabla u| dx + \lambda \int_{\Omega} u \int_{a \in \mathcal{A}} \left(p_1(a) - K(I(x)-a)\right)^2 dax
\]
\[
+\lambda \int_{\Omega} (1-u) \int_{a \in \mathcal{A}} \left(p_2(a) - K(I(x)-a)\right)^2 dax,
\]
(2.3)
where \( K \) is a symmetric Gaussian kernel
\[
K(z) = \frac{1}{\sqrt{2\pi\sigma}} \exp\left(-\frac{z^2}{2\sigma^2}\right),
\]
and \( \mathcal{A} \subset \mathbb{R} \) is the values domain of the image. However, the computation is expensive since it involves the integration in domain \( \mathcal{A} \).
2.3 Nonparametric method using mutual information

For two-phase image segmentation, Kim et al. [16] proposed to minimize the following energy

$$F(\vec{C}) = \alpha \int_{\vec{C}} ds - \frac{|\Omega|}{|\Omega_1|} \int_{\Omega_1} \log\left( P_1(I(x)) \right) dx - \frac{|\Omega|}{|\Omega_2|} \int_{\Omega_2} \log\left( P_2(I(x)) \right) dx,$$

(2.5)

where $\vec{C}$ is the curve of boundary $\partial \Omega_1$,

$$P_1(I(x)) = \frac{1}{|\Omega_1|} \int_{\Omega_1} K(I(x) - I(\hat{x})) d\hat{x}, \quad P_2(I(x)) = \frac{1}{|\Omega_2|} \int_{\Omega_2} K(I(x) - I(\hat{x})) d\hat{x},$$

and $K$ is a Gaussian kernel as defined in (2.4). The last two terms in the right hand side come from the mutual information. The derived curve evolution equation is

$$\frac{\partial \vec{C}}{\partial t} = \left[ \log \frac{P_1(I(\vec{C}))}{P_2(I(\vec{C}))} + \frac{1}{|\Omega_1|} \int_{\Omega_1} \frac{K(I(x) - I(\vec{C}))}{P_1(I(x))} dx ight. $$

$$- \left. \frac{1}{|\Omega_2|} \int_{\Omega_2} \frac{K(I(x) - I(\vec{C}))}{P_2(I(x))} dx \right] \vec{N} - \alpha \kappa \vec{N},$$

(2.6)

where $\kappa$ is the curvature of the curve $\vec{C}$ and $\vec{N}$ is the unit outward normal of $\vec{C}$. The computation is quite complicated, especially for multiphase image segmentation.

3 The proposed method

3.1 The proposed energy

We propose to use nonparametric probability density function in the region competition model which energy is

$$E(\Gamma) = \sum_{i=1}^{N} \mu_i \int_{\partial \Omega_i} ds - \sum_{i=1}^{N} \int_{\Omega_i} \log P_i(I, \Omega_i) dx.$$  

(3.1)

Here $P_i(I, \Omega_i)$ is the nonparametric probability density function which is determined by the intensity values of pixels in region $\Omega_i$. In the case of $N = 2$, the proposed energy is similar to (2.5). However, the numerical techniques are quite different. In the following, we will derive a quite simple and effective numerical method for the proposed model.

With a suitable change of the variables and parameters, (3.1) becomes

$$E(\chi) = \sum_{i=1}^{N} \int_{\Omega} |\nabla \chi_i| dx - \sum_{i=1}^{N} \lambda_i \int_{\Omega} \chi_i \log P_i(I, \chi_i) dx,$$  

(3.2)
where $\chi = (\chi_1, \ldots, \chi_N)$ and $\chi_i$ is the characteristic function of the region $\Omega_i$. The energy (3.2) is non-convex since the set of characteristic functions are not convex. To overcome this drawback, following the idea of [18], we replace the characteristic functions $\chi_i$ by fuzzy membership functions $u_i \in BV_{[0,1]}(\Omega)$. Note that $BV_{[0,1]}(\Omega)$ is the set of bounded variation functions valued in the interval $[0,1]$. Hence our new fuzzy region competition image segmentation model is to minimize the following energy

$$E(U, P) = \sum_{i=1}^{N} \int_{\Omega} |\nabla u_i| dx - \sum_{i=1}^{N} \int_{\Omega} \lambda u_i \log P_i(I, u_i) dx,$$

(3.3)

where the membership functions $\{u_i\}$ satisfies two constraints

(i) $u_i \in BV_{[0,1]}(\Omega)$, and (ii) $\sum_{i=1}^{N} u_i = 1$,

and $U = (u_1, \ldots, u_N)$, $P = (P_1, \ldots, P_N)$. Note that the term $\int_{\Omega} |\nabla u_i| dx$ is a total variation regularization term which is widely used in variational image processing.

For the purpose of efficiency in numerical method, we follow the idea in [2, 15, 18, 19] and take use of Chambolle’s fast dual projection algorithm [6]. For that end we add auxiliary variables $V = (v_1, \ldots, v_N)$, and approximate $E(U, P)$ by

$$\tilde{E}(U, V, P) = \sum_{i=1}^{N} \left( \int_{\Omega} |\nabla v_i| dx + \frac{1}{2\theta} \int_{\Omega} (v_i - u_i)^2 dx - \lambda \int_{\Omega} u_i \log P_i(I, u_i) dx \right),$$

(3.4)

where $\theta$ is chosen small enough such that $u_i$ and $v_i$ are almost identical with respect to the $L^2$ norm.

To make the constrained problem more easy to handle, we relax constraint (ii) by letting

$$u_N = 1 - \sum_{i=1}^{N-1} u_i,$$

(3.5)

and then further approximate the energy (3.4) by

$$E_r(U, \bar{V}, P) = \sum_{i=1}^{N-1} \int_{\Omega} |\nabla v_i| dx + \frac{1}{2\theta} \sum_{i=1}^{N-1} \int_{\Omega} (v_i - u_i)^2 dx$$

$$+ \lambda \sum_{i=1}^{N-1} \int_{\Omega} u_i \log \left( \frac{P_N(I, u_N)}{P_i(I, u_i)} \right) dx,$$

(3.6)

subject to

$$0 \leq u_i(x) \leq 1, \quad \text{for } i = 1:N-1,$$

(3.7)

where $\bar{V} = (v_1, \ldots, v_{N-1})$. 

3.2 Energy minimization

To find the minimizer of energy $E_r$ in (3.6) under the constraint (3.7), we use an alternate minimization method.

3.2.1 Solving $\bar{U}$

For fixed $\bar{P}$ and $\bar{V}$, we solve $\bar{U} = (u_1, \cdots, u_{N-1})$ by minimizing

$$E_1(\bar{U}) = \frac{1}{2\theta} \sum_{i=1}^{N-1} \int_{\Omega} (v_i - u_i)^2 dx + \lambda \sum_{i=1}^{N-1} \int_{\Omega} u_i \log \left( \frac{P_N}{P_i} \right) dx,$$

subject to

$$0 \leq u_i(x) \leq 1, \text{ for } i = 1 : N - 1.$$

Since the objective function is strictly convex and the feasible region is convex, there exists a unique global minimizer $\bar{U}^* = (u_1^*, \cdots, u_{N-1}^*)$ of (3.8) and the following KKT conditions [17] are both necessary and sufficient: Suppose $\tilde{U}^*$ is the global minimizer of (3.8), then

(a) $u_i^*(x) \geq 0$, $1 - u_i^*(x) \geq 0$;

(b) There exist Lagrange multipliers $\beta_i^*(x)$ and $\gamma_i^*(x)$, for each point $x \in \Omega$, such that

$$\frac{\partial E_1(\bar{U})}{\partial u_i^*(x)} = \lambda \log \left( \frac{P_N(x)}{P_i(x)} \right) + \frac{1}{\theta} \left( u_i^*(x) - v_i(x) \right) = \beta_i^*(x) - \gamma_i^*(x);$$

(c) $\beta_i^*(x) u_i^*(x) = 0$, $\gamma_i^*(x) (1 - u_i^*(x)) = 0$;

(d) $\beta_i^*(x) \geq 0$, $\gamma_i^*(x) \geq 0$;

for $i = 1 : N - 1$.

First we assume $\tilde{U} = (\tilde{u}_1, \cdots, \tilde{u}_{N-1})$ satisfies

$$\lambda \log \left( \frac{P_N(x)}{P_i(x)} \right) + \frac{1}{\theta} \left( \tilde{u}_i(x) - v_i(x) \right) = 0.$$

The solution is

$$\tilde{u}_i = v_i - \lambda \theta \log \left( \frac{P_N}{P_i} \right).$$

Then we construct $\hat{u}_i$ by projecting $\tilde{u}_i$ on $[0,1]$, that is $\hat{u}_i := \min \{ \max \{ \tilde{u}_i, 0 \}, 1 \}$. Let

$$\eta_i(x) = \lambda \log \left( \frac{P_N(x)}{P_i(x)} \right) + \frac{1}{\theta} \left( \hat{u}_i(x) - v_i(x) \right).$$

For each $x \in \Omega$, we choose $\hat{\beta}_i(x)$ and $\hat{\gamma}_i(x)$ as follows:

if $\hat{u}_i(x) \in (0,1)$, then we set $\hat{\beta}_i(x) := 0$ and $\hat{\gamma}_i(x) := 0$;

if $\hat{u}_i(x) = 0$, then we set $\hat{\beta}_i(x) := \eta_i(x) \geq 0$ and $\hat{\gamma}_i(x) := 0$;
if $\hat{u}_i(x) = 1$, then we set $\hat{\beta}_i(x) := 0$ and $\hat{\gamma}_i(x) := -\eta_i(x) \geq 0$.

It is easy to verify that $\{\hat{u}_i, \hat{\beta}_i, \hat{\gamma}_i\}$ satisfies KKT conditions (a)-(d). Therefore $\hat{U}$ is a minimizer of energy (3.8) and by uniqueness $\tilde{U}^* = \hat{U}$.

Then we conclude that the closed form solution of $u_i, i = 1:N-1$ is given by

$$u_i = \max \left\{ \min \left\{ v_i - \lambda \theta \log \left( \frac{P_N}{P_i} \right), 1 \right\}, 0 \right\}, \quad (3.9)$$

and $u_N$ is given by (3.5).

### 3.2.2 Estimation of $P$

Let us first give a brief introduction of nonparametric kernel density estimation method. If $y_1, y_2, \ldots, y_n \sim f$ is an independent and identically-distributed sample of a random variable, then the kernel density approximation of its probability density function (pdf) is

$$\hat{f}_h(y) = \frac{1}{nh} \sum_{j=1}^{n} K\left( \frac{y - y_j}{h} \right), \quad (3.10)$$

where $K$ is some kernel and $h$ is the bandwidth (smoothing parameter) [24]. In the proposed method $K$ is taken to be a standard Gaussian kernel with mean zero and variance 1, i.e.,

$$K(z) = \frac{1}{\sqrt{2\pi}} \exp \left( -\frac{z^2}{2} \right). \quad (3.11)$$

We use the optimal bandwidth [1] for the Gaussian kernel density estimation, which is

$$h = (4/3n)^{1/5} \sigma,$$

where $\sigma$ denotes the standard deviation of the distribution. A robust estimate of $\sigma$ is the median absolute deviation estimator

$$\sigma = \text{median}\{|y_j - \mu|\}/0.6745,$$

where $\mu$ denotes the median of the sample. Remark that this pdf estimation is implemented by the function $ksdensity.m$ in Matlab toolbox and we take use of it in our numerical implementation.

In our problem, for fixed $U$ and $\tilde{V}$, we need to estimate the probability density function $P_i(I, u_i)$ using the above method with Gaussian kernel. In the discrete form, assume the image $I$ is a $p \times q$ matrix and $I(k,l), 1 \leq k \leq p, 1 \leq l \leq q$ denotes the intensity of the grid $(k,l)$. Then we need to estimate the probability $P_i(k,l)$ at each grid. Now the question is how to choose $y, y_j$ in (3.10), and how to assign the value of $P_i(k,l)$ from the estimated pdf $\hat{f}_h(y)$. In the simplest case of $N = 2$, most of the intensity values can be classified into two categories: $I(k,l) \in R_i$, if $u_i(k,l) > 0.5$. Then the intensity values in class $R_i$ are regarded as
sample \{y_j\}. Since the range of the image is [0,255], we choose \(y = [0:255]\) as the integers between 0 and 255. Hence we can estimate the pdf \(f_h(y)\) using formula (3.10). Finally, we assign \(P_i(k,l) = f_h(I(k,l))\).

When the class number \(N \geq 3\), \(P_i, i = 1, \ldots, N - 1\) is estimated as the case of \(N = 2\). Remark that the \(N\)th class is different from the other classes due to the relaxation (3.5) of the constraint (ii). Hence we use a non-uniform formula to estimate \(P_N\) in order to overcome the errors of chosen sample in the \(N\)th class. We estimate \(P_N\) in the term \(\log(P_N/P_i)\) by formula (3.10), where the sample is all the intensity values \(I(k,l)\) satisfying \(u_i(k,l) < 0.5\).

### 3.2.3 Solving \(\bar{V}\)

By fixing \(P\) and \(U\), the variables \(\bar{V}\) can be solved by minimizing

\[
\int_\Omega |\nabla v_i|dx + \frac{1}{2\theta} \int_\Omega (v_i - u_i)^2dx, \quad i = 1, \ldots, N - 1. \tag{3.12}
\]

This problem can be efficiently solved by fast duality projection algorithm. The solution is given by

\[
v_i = u_i - \theta \text{div} p_i, \tag{3.13}
\]

where the vector \(p_i\) can be solved by fixed point method: initializing \(p_i^0 = 0\), and iterating

\[
p_i^{n+1} = \frac{p_i^n + \tau \nabla (\text{div} p_i^n - u_i/\theta)}{1 + \tau |\nabla (\text{div} p_i^n - u_i/\theta)|},
\]

with \(\tau \leq 1/8\) to ensure convergence. See [6] for more details. Furthermore, for this minimization problem, we can prove the existence and uniqueness of minimizer. We can also prove that the range of \(v_i\) is \([0,1]\), if \(u_i \in [0,1]\). It is the following proposition.

**Proposition 3.1.** There exists a unique minimizer \(v^*\) to minimization problem

\[
\min_{v \in BV(\Omega) \cap L^2(\Omega)} \left\{ \int_\Omega |Dv|dx + \frac{1}{2\theta} \int_\Omega (v - u)^2dx \right\}, \tag{3.14}
\]

where \(0 \leq u \leq 1\). Moreover, \(v^*\) satisfies maximum principle

\[
0 \leq \text{ess inf}_\Omega u \leq v^* \leq \text{ess sup}_\Omega u \leq 1. \tag{3.15}
\]

Remark that in the energy, we use \(\int_\Omega |Dv|dx\) instead of \(\int_\Omega |\nabla v|dx\), in order to indicate that the derivative is actually a measure. The proof of Proposition 3.1 can be found in the appendix.
3.3 The algorithm

The algorithm of minimizing $E$ can be summarized in the following four steps:

1. Initialize the membership functions $u_i, i=1:N$, such that the constraints (i) and (ii) are both satisfied;
2. Estimate $P_i$ by the method in Section 3.2.2;
3. Update $v_i$ by formula (3.13) for $i=1:N-1$;
4. Update $u_i$ by formula (3.9) for $i=1:N-1$ and (3.5) for $i=N$.

Repeat Steps 2-4 until termination. The termination criterion is as follows

$$\|U_{new} - U_{old}\| \leq \epsilon,$$

where $\|\cdot\|$ denotes the Euclidean distance, and $\epsilon$ is a small positive number.

4 Experimental results

We test our algorithm on various images include synthetic texture images, natural images and synthetic aperture radar (SAR) images which appear in the recent image segmentation literatures. We display the segmentation results by paint the contour $u_i = 0.5$ ($i=1:N-1$) with different colors on the original image. The membership functions are also displayed for illustration. Some of our results are compared with other state-of-the-art segmentation methods. In the numerical implementation, the fixed parameters are $\theta = 0.1, \tau = 0.125$. $\lambda$ is a parameter that need to be tuned.

Test 1: Two-phase segmentation for synthetic texture images. Fig. 1 shows six synthetic texture images with the two-phase segmentation results by the proposed algorithm. The results are satisfactory. Parameters for the six images from left to right and up to bottom are $\lambda = 0.3, \lambda = 0.2, \lambda = 0.2, \lambda = 0.2, \lambda = 0.1, \lambda = 0.2$ in turn.

Test 2: Two-phase segmentation for synthetic images satisfying different distributions. We test synthetic images generated by several sets of distributions in Fig. 2 as used in [16]. In Fig. 2(a) the two distributions for the foreground and the background are Gaussian with different means and the same variance. In Fig. 2(d) the two distributions for the foreground and the background are Gaussian with the same mean and different variances. For these two cases, the method of Yezzi et al. [30] would require the selection of the appropriate statistic (i.e., the means and variances for the first and second cases, respectively) a priori, whereas our method solves the segmentation problem without a prior information. We see from Fig. 2 that the result is as well as that given in [16]. Fig. 2(g) shows a challenging case. The underlying distributions of the foreground and the background are a unimodal Gaussian density and a bimodal density with two Gaussian components as illustrated in Fig. 7(c)-(d) in [16]. The two distributions have the same mean and same variance, so it is hard even for a human observer to separate the
Figure 1: Two-phase segmentation for synthetic texture images. The First and Fourth columns: synthetic images; the Second and Fifth columns: segmentation results; the Third and Sixth columns: membership functions $u_1$. Parameters: $\lambda = 0.3$ for (a); $\lambda = 0.2$ for (d); $\lambda = 0.2$ for (g); $\lambda = 0.2$ for (j); $\lambda = 0.1$ for (m); $\lambda = 0.2$ for (p).

Figure 2: Two-phase segmentation for synthetic images satisfying different distributions. The First column: synthetic images; the Second column: segmentation results of the proposed method; the Third column: membership functions $u_1$ in the proposed method; the Fourth column: segmentation results by method in [16]. Parameters: $\lambda = 0.2$ for (a); $\lambda = 0.2$ for (e); $\lambda = 0.3$ for (i).
foreground from the background. However, our method still gives good segmentation results which are competitive with the results by method in [16]. Parameters for Fig. 2(a), Fig. 2(e) and Fig. 2(i) are $\lambda = 0.2$, $\lambda = 0.2$ and $\lambda = 0.5$ respectively.

**Test 3: Two-phase segmentation for natural texture images.** In Fig. 3, three natural texture images are tested. Compared with the results of the state-of-the-art works showed in Fig. 3, our results are also satisfactory. Parameters for the proposed method for the three images are $\lambda = 0.2$, $\lambda = 0.3$ and $\lambda = 0.3$ in turn.

**Test 4: Three-phase image segmentation.** In Fig. 4, we test our method with 3-phase image segmentation. The segmentation results are still satisfactory. Parameters for Fig. 4(a) and Fig. 4(e) are $\lambda = 0.2$ and $\lambda = 0.3$ respectively.

**Test 5: Four-phase image segmentation.** In Fig. 5, we test our method with 4-phase image segmentation. The segmentation results are satisfactory. The parameter is $\lambda = 0.3$.

**Test 6: Sensitivity to initialization (two-phase case).** In Fig. 6, we illustrate the evolution of membership function with different initializations for the zebra image in Fig. 3(e). In Fig. 6(a) and Fig. 6(e), we initialize $u_1 = 1$ in the white circle, and otherwise $u_1 = 0$. In Fig. 6(i), we set the initial membership function $u_1 = I/255$. In Fig. 6(m), we choose the initial membership function randomly valued in $[0,1]$. Fig. 6 shows that our method is not sensitive to initialization which is a drawback of active contour based method. However, the running time of the proposed method depends on the initialization. Good initial-
Figure 4: Three-phase image segmentation. The First column: synthetic images; the Second column: segmentation results; the Third column: membership functions $u_1$; the Fourth column: membership functions $u_2$. Parameters: $\lambda = 0.2$ for (a), $\lambda = 0.3$ for (e).

Figure 5: Four-phase image segmentation. (a) synthetic image; (b) segmentation result; (c) membership function $u_1$; (d) membership function $u_2$; (d) membership function $u_3$. Parameter: $\lambda = 0.3$.

ization such as Fig. 6(a) converges faster than other initializations. We remark that by experience, the best initialization in terms of speed is obtained by choosing characteristic function of a region inside the object to be segmented. The parameter is $\lambda = 0.3$.

Test 7: Sensitivity to initialization (three-phase case). Remark that for $N \geq 3$, the algorithm is also sensitive to initialization of membership functions. A good initialization of $u_i, i = 1, \ldots, N - 1$ is given by first choosing a part almost inside the $i$-th texture region and then initializing $u_i = 1, u_j = 0, j \neq i$ in that region. This initialization method is used to get the results for $N \geq 3$ in this paper if not specified. In Fig. 7, we show two initializations of Fig. 4(e). One gives the correct result (First row) and the other gives the wrong result (Second row). We can see from Fig. 7(g) and Fig. 7(h) that $u_1 + u_2 \approx 1, u_3 \approx 0$, thus the image is finally segmentated into two regions but not three regions. The parameter is $\lambda = 0.3$.

In the following, we make comparison with our method and the anisotropic heat diffusion based method in [12] for SAR image segmentation. SAR image segmentation is
Figure 6: Sensitivity to initialization (two-phase case). The figure displays the evolution of the membership functions with different initializations on a zebra image Fig. 3(e). The final results from top to bottom are obtained at iterations 105, 270, 150 and 240 respectively. Parameter: $\lambda = 0.3$.

Figure 7: Sensitivity to initialization (three-phase case). The test image is Fig. 4(e). The First row: initialization 1 gives the correct result. Second row: initialization 2 gives the wrong result. Parameter: $\lambda = 0.3$. 
usually said to be a complex problem in the pattern recognition area, due to the presence of speckle derived from the coherency of the image formation process. Since the pdf of the speckle noise follows some distribution, we can expect that the proposed segmentation model can segment this kind of image.

**Test 8: Two-phase segmentation for a SAR image.** Fig. 8(a) is a test SAR image contains Wujiang river in China which is tested in [12]. The water area is extracted in Fig. 8(d) by their method. Our method gives satisfactory segmentation results in Fig. 8(b) with a more accurate and smoother boundary. We take $\lambda = 0.08$ for this image.

**Test 9: Three-phase segmentation for a SAR image.** Fig. 9(a) shows a real MSTSAR SAR image of vehicle T72. This image mainly contains three regions: background, target and shadow. Fig. 9(b) shows the three-phase segmentation result of our proposed method. Fig. 9(c) and Fig. 9(d) display the membership functions $u_1$ and $u_2$. Our result is competitive with the result Fig. 9(e) by method in [12]. We take $\lambda = 0.2$ for this image.

## 5 Conclusions

A general multiphase fuzzy region competition model for texture image segmentation is proposed in this paper. There are two novelties. One is that a fuzzy membership function is introduced to represent a region for handling multiphase segmentation. The other is the use of kernel density estimation with optimal bandwidth to estimate the probabil-
ity density function in each region represented by the fuzzy membership function. The proposed method is faster and easier to implement than the other curve evolution based methods. According to our experimental results, we find that our method is competitive with other state-of-the-art segmentation methods for texture images and SAR images. In the future work, we will extend the proposed method to vector valued images.

Appendix

Proof of Proposition 3.1. Define \( \varphi \) and \( \varphi_\varepsilon \) on \( \mathbb{R}^n \) by

\[
\varphi(p) = |p|, \quad \varphi_\varepsilon(p) = \frac{1}{1+\varepsilon} |p|^{1+\varepsilon},
\]

for \( \varepsilon > 0 \), and consider the following minimization problem

\[
\min_{v \in W^{1,1+\varepsilon}(\Omega) \cap L^2(\Omega)} \left\{ E_\varepsilon(v) = \int_\Omega \varphi_\varepsilon(\nabla v)dx + \frac{1}{2\theta} \int_\Omega (v-u)^2dx \right\}.
\]

It can be verified that \( E_\varepsilon(v) \) is lower semi-continuous since \( W^{1,1+\varepsilon}(\Omega) \cap L^2(\Omega) \) is a reflexive Banach space and \( E_\varepsilon(v) \) is strictly convex. By standard variational methods, there is a unique solution \( v_\varepsilon \) to this problem. We fix \( \varepsilon > 0 \), \( t \geq 0 \) and let \( w = \min\{v_\varepsilon, t\} \). Noting that

\[
w \in W^{1,1+\varepsilon}(\Omega) \cap L^2(\Omega),
\]

with

\[
\nabla w = \begin{cases} 
\nabla v_\varepsilon, & \text{if } v_\varepsilon < t, \\
0, & \text{if } v_\varepsilon \geq t,
\end{cases}
\]

we have

\[
\int_\Omega \varphi_\varepsilon(\nabla v_\varepsilon)dx + \frac{1}{2\theta} \int_\Omega (v_\varepsilon-u)^2dx \leq \int_\Omega \varphi_\varepsilon(\nabla w)dx + \frac{1}{2\theta} \int_\Omega (w-u)^2dx,
\]

and thus after subtracting

\[
\int_{\{v_\varepsilon \geq t\}} \varphi_\varepsilon(\nabla v_\varepsilon)dx + \frac{1}{2\theta} \int_{\{v_\varepsilon \geq t\}} (v_\varepsilon-u)^2dx \leq \frac{1}{2\theta} \int_{\{v_\varepsilon \geq t\}} (t-u)^2dx.
\]

Hence

\[
\int_{\{v_\varepsilon \geq t\}} (v_\varepsilon-u)^2dx \leq \int_{\{v_\varepsilon \geq t\}} (t-u)^2dx.
\]

Setting \( t = \text{esssup}_\Omega u \), we see that if \( \text{esssup}_\Omega v_\varepsilon > t \). Then

\[
\int_{\{v_\varepsilon \geq t\}} (t-u)^2dx < \int_{\{v_\varepsilon \geq t\}} (v_\varepsilon-u)^2dx,
\]
which contradicts (A.2). Applying a similar argument to $w = \min \{ v_\epsilon, t \}$, for $t = \text{essinf}_\Omega u$, we get $v_\epsilon \geq \text{essinf}_\Omega u$. Then

$$0 \leq \text{essinf}_\Omega u \leq v_\epsilon \leq \text{esssup}_\Omega u \leq 1.$$ \hspace{1cm} (A.3)

Furthermore, since (A.1) holds for any $w \in W^{1,1+\epsilon}(\Omega) \cap L^2(\Omega)$, letting $w = 0$ in (A.1), we see that $v_\epsilon$ is bounded in $W^{1,1+\epsilon}(\Omega) \cap L^2(\Omega)$ independent of $\epsilon$. Thus there exists a $v_* \in BV(\Omega) \cap L^2(\Omega)$, and a subsequence of $\{ v_\epsilon \}$, still denoted by $\{ v_\epsilon \}$, such that $v_\epsilon \rightharpoonup v_*$ strongly in $L^1(\Omega)$, $v_\epsilon \rightharpoonup v_*$ weakly in $L^2(\Omega)$, and $v_\epsilon \rightarrow v_*$ a.e. in $\Omega$. Letting $\epsilon \rightarrow 0$ in (A.1), noting that $\phi(p) \leq \phi_\epsilon(p)$, for all $p$, lower semicontinuity of the functional $\int_\Omega \phi(p)dx$ on $BV(\Omega)$, and the lower semicontinuity of $L^2$ norm, we get

$$\int_\Omega \phi(Dv_*)dx + \frac{1}{2\theta} \int_\Omega (v_* - u)^2dx \leq \int_\Omega \phi(\nabla w)dx + \frac{1}{2\theta} \int_\Omega (w - u)^2dx,$$ \hspace{1cm} (A.4)

for all $w \in W^{1,1+\epsilon}(\Omega) \cap L^2(\Omega)$. Note that for any $w \in BV(\Omega) \cap L^2(\Omega)$, there exists a sequence $w_n$ in $C^\infty(\bar{\Omega})$, such that

$$\int_\Omega \phi(\nabla w_n)dx \rightarrow \int_\Omega \phi(\nabla w)dx,$$ 

and $w_n \rightarrow w$ strongly in $L^2(\Omega)$ [13]. Hence (A.4) holds for all $w \in BV(\Omega) \cap L^2(\Omega)$, and then $v_*$ is a minimizer of problem (3.14). The uniqueness of minimizer follows by the strict convexity of the energy functional in (3.14). By inequality (A.3), $v_*$ satisfies maximum principle (3.15). \hspace{1cm} \square
