## Abstract

Cycles are the only 2-connected graphs in which any two nonadjacent vertices form a vertex cut. We generalize this fact by proving that for every integer  $k \geq 3$  there exists a unique graph  $G$  satisfying the following three conditions: (1)  $G$  is  $k$ -connected; (2) the independence number of  $G$  is greater than  $k$ ; (3) any independent set of cardinality  $k$  is a vertex cut of  $G$ . However, the edge version of this result does not hold. We also consider the problem when replacing independent sets by the periphery.

**Keywords** Vertex cut · Connectivity · Independent set

**Mathematics Subject Classification** 05C40 · 05C69

We consider finite simple graphs. For terminology and notations we follow the books [2, 5]. It is known [4, p. 46] that cycles are the only 2-connected graphs in which any two nonadjacent vertices form a vertex cut. We will generalize this fact and consider two related problems.

We denote by  $V(G)$  the vertex set of a graph  $G$ . The order of  $G$ , denoted by  $|G|$ , is the number of vertices of  $G$ . For  $S \subseteq V(G)$ , the notation  $G[S]$  denotes the subgraph of  $G$  induced by  $S$ . Let  $K_{s,t}$  denote the complete bipartite graph whose partite sets have cardinality  $s$  and  $t$ , respectively.

**Notation.** The notation  $K_{s,s} - PM$  denotes the graph obtained from the balanced complete bipartite graph  $K_{s,s}$  by deleting all the edges in a perfect matching of  $K_{s,s}$ .

Note that  $K_{s,s} - PM$  is an  $(s - 1)$ -connected  $(s - 1)$ -regular graph,  $K_{3,3} - PM$  is the 6-cycle  $C_6$  and  $K_{4,4} - PM$  is the cube  $Q_3$ .

**Theorem 1** *Let  $k \geq 3$  be an integer. Then  $K_{k+1,k+1} - PM$  is the unique graph  $G$  satisfying the following three conditions: (1)  $G$  is  $k$ -connected; (2) the independence number of  $G$  is greater than  $k$ ; (3) any independent set of cardinality  $k$  is a vertex cut of  $G$ .*

**Proof** It is easy to verify that the graph  $K_{k+1,k+1} - PM$  indeed satisfies the three conditions in Theorem 1.

Conversely, let  $G$  be a graph satisfying the three conditions in Theorem 1. We first assert that  $G$  has order at least  $2k + 2$ . Let  $S$  be an independent set of  $G$  with cardinality  $k + 1$ . Since  $G$  is  $k$ -connected, every vertex has degree at least  $k$ . Let  $T$  be the neighborhood of one vertex in  $S$ . Then  $|T| \geq k$ . Thus  $|G| \geq |S| + |T| \geq 2k + 1$ . If  $|G| = 2k + 1$ , then  $T$  would be the common neighborhood of all the vertices in  $S$ . But now any  $k$  vertices in  $S$  do not form a vertex cut, contradicting condition (3). This shows that  $|G| \geq 2k + 2$ .

Choose an arbitrary but fixed independent set  $A = \{x_1, x_2, \dots, x_{k+1}\}$  of cardinality  $k + 1$  in  $G$ . By condition (3), for every  $i$  with  $1 \leq i \leq k + 1$ , the graph  $H_i \triangleq G - (A \setminus \{x_i\})$  is disconnected. Let  $G_i$  denote the union of all the components of  $H_i$  except the component containing  $x_i$ . Note that each  $G_i$  is disjoint from the set  $A$ .

Let  $Q$  and  $W$  be subgraphs of  $G$  or subsets of  $V(G)$ . We say that  $Q$  and  $W$  are *adjacent* if there exists an edge with one endpoint in  $Q$  and the other endpoint in  $W$ ; otherwise  $Q$  and  $W$  are *nonadjacent*. Next we prove three claims.

Claim 1.  $V(G_i) \cap V(G_j) = \phi$ ,  $G_i$  and  $G_j$  are nonadjacent for  $1 \leq i < j \leq k + 1$ .

In the sequel, for notational simplicity, a vertex  $v$  may also mean the set  $\{v\}$ . We will use the fact that if  $T$  is a minimum vertex cut of  $G$ , then every vertex in  $T$  has a neighbor in every component of  $G - T$ . Clearly,  $G$  has connectivity  $k$ . Since  $A \setminus x_j$  is a minimum vertex cut of  $G$ , the subgraph  $G[x_i \cup V(G_j)]$  is connected and it is contained in the component of  $H_i$  containing  $x_i$ . By the definition of  $G_i$ , we deduce that  $(x_i \cup V(G_j)) \cap V(G_i) = \phi$ , implying  $V(G_i) \cap V(G_j) = \phi$ .

To show the second conclusion, just note that any vertex in  $G_i$  and any vertex in  $G_j$  lie in different components of the graph  $G - (A \setminus x_i)$ .

Claim 2.  $A \cup (\bigcup_{i=1}^{k+1} V(G_i)) = V(G)$ .

To the contrary, suppose that  $F \triangleq V(G) \setminus \{A \cup (\bigcup_{i=1}^{k+1} V(G_i))\}$  is not empty. Let  $F_1, F_2, \dots, F_s$  be the components of  $G[F]$ .

Recall that by definition, for  $1 \leq i \leq k + 1$ ,  $G_i$  denotes the union of all the components of  $G - (A \setminus x_i)$  except the component  $R_i$  that contains  $x_i$ . Hence, for every  $p$  with  $1 \leq p \leq s$ ,  $F_p$  is a subgraph of  $R_i$ , implying that  $G_i$  is nonadjacent to  $F_p$ . Note that

$$R_i = G \left[ x_i \cup F \cup \left( \bigcup_{j \neq i} V(G_j) \right) \right].$$

Since  $R_i$  is connected,  $x_i$  is adjacent to every component of  $G_j$  with  $j \neq i$  and  $x_i$  is adjacent to each  $F_p$  for  $1 \leq p \leq s$ . Thus, every  $F_p$  is adjacent to every vertex in  $A$ .

We choose one vertex  $y_i$  from  $G_i$  for each  $1 \leq i \leq k$ . Then  $B \triangleq \{y_1, y_2, \dots, y_k\}$  is an independent set of  $G$ . We assert that every component of  $(\bigcup_{i=1}^{k+1} G_i) - B$  is adjacent to  $A$ , since otherwise  $G$  would have a cut-vertex. It follows that  $G - B$  is connected, contradicting condition (3). This shows that  $F$  is empty and claim 2 is proved.

Claim 3.  $|G_i| = 1$  for every  $1 \leq i \leq k + 1$ .

To the contrary, we suppose that some  $G_i$  has order at least 2. Without loss of generality, suppose  $|G_k| \geq 2$ . Let  $z_j$  be a neighbor of  $x_{k+1}$  in  $G_j$  for  $j = 1, \dots, k - 1$ . Since  $x_{k+1}$  is adjacent to  $G_k$ ,  $x_{k+1}$  has a neighbor  $w \in G_k$ . The condition  $|G_k| \geq 2$  ensures that  $G_k$  has a vertex  $z_k$  distinct from  $w$ . Denote  $C = \{z_1, z_2, \dots, z_k\}$ . Then  $C$  is an independent set. We assert that every component of  $(G_1 \cup G_2 \cup \dots \cup G_k) - C$  is adjacent to  $A \setminus x_{k+1}$ , since otherwise some  $z_j$  and  $x_{k+1}$  would form a vertex cut of  $G$ , contradicting the condition that  $G$  is  $k$ -connected and  $k \geq 3$ . Also, every component of  $G_{k+1}$  is adjacent to every vertex in  $A \setminus x_{k+1}$ . It follows that the graph  $G - (C \cup x_{k+1})$  is connected. But  $x_{k+1}$  is adjacent to  $w$ , a vertex in  $G_k - z_k$ . Hence  $G - C$  is connected, contradicting condition (3). This shows that each  $G_i$  consists of one vertex.

Combining the information in the above three claims, we deduce that  $|G| = 2k + 2$  and the neighborhood of  $x_i$  is  $\{G_1, G_2, \dots, G_{k+1}\} \setminus \{G_i\}$  for  $1 \leq i \leq k + 1$ . It follows that  $G = K_{k+1, k+1} - PM$ . This completes the proof.  $\square$

Feng Liu [3] asked whether the edge version of Theorem 1 holds. The following result shows that the answer is negative.

**Corollary 2** *Let  $k \geq 3$  be an integer. If a graph  $G$  is  $k$ -edge-connected with matching number greater than  $k$ , then  $G$  contains a matching  $M$  of cardinality  $k$  such that  $G - M$  is connected.*

**Proof** To the contrary, suppose that for any matching  $M$  of cardinality  $k$ ,  $G - M$  is disconnected. Consider the line graph of  $G$ , denoted by  $H \triangleq L(G)$ . Since  $G$  is  $k$ -edge-connected, we deduce that [5, p. 283]  $H$  is  $k$ -connected. An independent set of vertices in  $H$  corresponds to a matching in  $G$ . Applying Theorem 1 to  $H$  we have  $H = K_{k+1, k+1} - PM$ , where we use the equality sign for graphs to mean isomorphism. It is known ([1] or [5, p. 282]) that any line graph of a simple graph cannot have the claw as an induced subgraph. However, for  $k \geq 3$ ,  $K_{k+1, k+1} - PM$  contains an induced claw (many in fact). This contradiction shows that  $G$  contains a matching  $M$  of cardinality  $k$  such that  $G - M$  is connected.  $\square$

**Remark** As for the case  $k = 2$  of Corollary 2, using the ideas in the above proof and using the fact mentioned at the beginning of this paper, we see that cycles are the only 2-edge-connected graphs in which any two nonadjacent edges form a separating set.

Finally, we consider replacing independent vertices in Theorem 1 by peripheral vertices. The *eccentricity* of a vertex  $v$  in a graph  $G$ , denoted by  $e(v)$ , is the distance to a vertex farthest from  $v$ . A vertex  $v$  is a *peripheral vertex* of  $G$  if  $e(v)$  is equal to the diameter of  $G$ . The *periphery* of  $G$  is the set of all peripheral vertices. We pose the following conjecture.

Fig. 1 The graph  $F$ 

**Conjecture 3** Let  $k \geq 2$  be an integer. If  $G$  is a  $k$ -connected graph whose periphery has cardinality at least  $k$ , then  $G$  contains a set  $S$  of  $k$  peripheral vertices such that  $G - S$  is connected.

**Observation 4** The case  $k = 2$  of Conjecture 3 is true.

**Proof** To the contrary, suppose that any two peripheral vertices form a vertex cut of  $G$ . Denote by  $d(u, v)$  the distance between two vertices  $u, v$  and let the diameter of  $G$  be  $d$ . We have  $d \geq 2$ . Choose vertices  $x, y$  such that  $d(x, y) = d$ . Let  $P$  be a shortest  $(x, y)$ -path, and let  $y'$  be the neighbor of  $y$  on  $P$ . Let  $H$  be a component of  $G - \{x, y\}$  that does not contain the path  $P - \{x, y\}$ .

Since  $G$  is 2-connected, both  $x$  and  $y$  have a neighbor in  $H$ . Let  $x'$  be a neighbor of  $x$  in  $H$ . Then  $d(x', y) \geq d - 1$ . Since every  $(x', y)$ -path contains either  $x$  or  $y$ , we deduce that  $d(x', y) = d$ . Thus  $x'$  is also a peripheral vertex. By our assumption,  $G - \{x, x'\}$  is disconnected. Let  $R$  be the component of  $G - \{x, x'\}$  containing  $y$ . Clearly every component of  $G - \{x, x'\}$  other than  $R$  is contained in  $H$ . Let  $Q$  be an arbitrary such component. We assert that every vertex in  $Q$  is adjacent to  $x'$ . Let  $z \in V(Q)$ . Any  $(z, y)$ -path must contain either  $x$  or  $x'$ . Since  $d(x, y) = d$ , a shortest  $(z, y)$ -path must contain  $x'$ , which implies that  $z$  and  $x'$  are adjacent and  $z$  is a peripheral vertex, since  $d(x', y) \geq d - 1$ . Choose a vertex  $z_0$  from any component of  $G - \{x, x'\}$  other than  $R$ . Note that  $x'$  is adjacent to  $R$ , since  $\{x, x'\}$  is a minimum vertex cut of  $G$ . Thus, the graph  $G - \{x, z_0\}$  is connected, contradicting our assumption.  $\square$

The graph  $F$  in Fig. 1 shows that the connectivity condition in Conjecture 3 cannot be dropped.  $F$  has diameter 4 and periphery  $\{v_1, v_2, v_3, v_4, v_5, v_6\}$ . With  $k = 5$ , any 5 peripheral vertices of  $F$  form a vertex cut.
